

Title: The Water Cycle

The water cycle is a continuous process by which water moves through the Earth's atmosphere, surface, and underground. It involves several stages, including evaporation, condensation, precipitation, and collection.

Evaporation: Water from oceans, rivers, and lakes is heated by the sun, turning it into vapor that rises into the atmosphere.

Condensation: As the water vapor cools, it condenses to form clouds.

Precipitation: When these clouds become heavy, they release water in the form of rain, snow, or hail.

Collection: The fallen water collects in water bodies like lakes, oceans, and underground reservoirs, continuing the cycle.

This cycle is crucial in maintaining Earth's ecosystem.
